# What makes a computer a computer?

- To simply put a computer is a machine made up of multiple components that works together to process, store and display information.

A computer consists of:

- Cpu, think of it as a brain of the computer
- Gpu, process graphics and parallel tasks
- Ram, temporarily holds active data
- Storage, a storage for your computer to store files
- Motherboard , this connects all components together
- PSU, just provides power

Note: alot of your automated or smart items is a computer :D

# CPU AND GPU

Both are processors but specialize in their own jobs, where the cpu handles general tasks and instructions, while gpu is designed to handle a massive  amounts of calculations at the same time.

Cpu has stronger but lesser cores while gpus has many cores but lesser

Example of how it works:

Cpu calculates the game, then gpu renders it for your monitor to display the final image

## CPU

- Central processing unit
- handles instruction and calculations
- Good at doing generally different types of task

## GPU

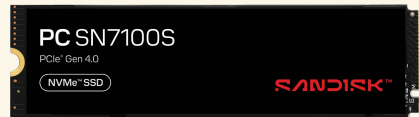

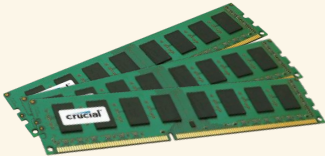

- graphics processing unit
- Handles the rendering
- Also is what is used to display something on the screen

# RAM AND STORAGE(HHD, SSD, SD, ETC)

Both are used to store data, but they specialize in different jobs. Ram temporarily holds the data that the computer is actively using. While storage which you know as a ssd, hdd keeps files, programs, and other data.

Ram is very fast, but has a very limited amount of space, this is for apps to store info for the cpu and gpu to quickly access quickly. While storage is slower but able to carry large amounts of data.

Theres alot of different types of storage a computer can use being a hdd slow but can carry large amounts of data, ssd fast but expensive

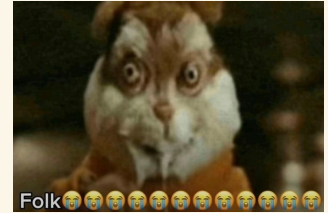

## RAM

- Random access memory
- Temporarily stores data
- Very Fast
- Data is lost when the computer is lost

## storage

- Stores files, programs, and the operating system
- Keeps data even when the computer is off
- Slower than ram(very)

# The rest of the parts

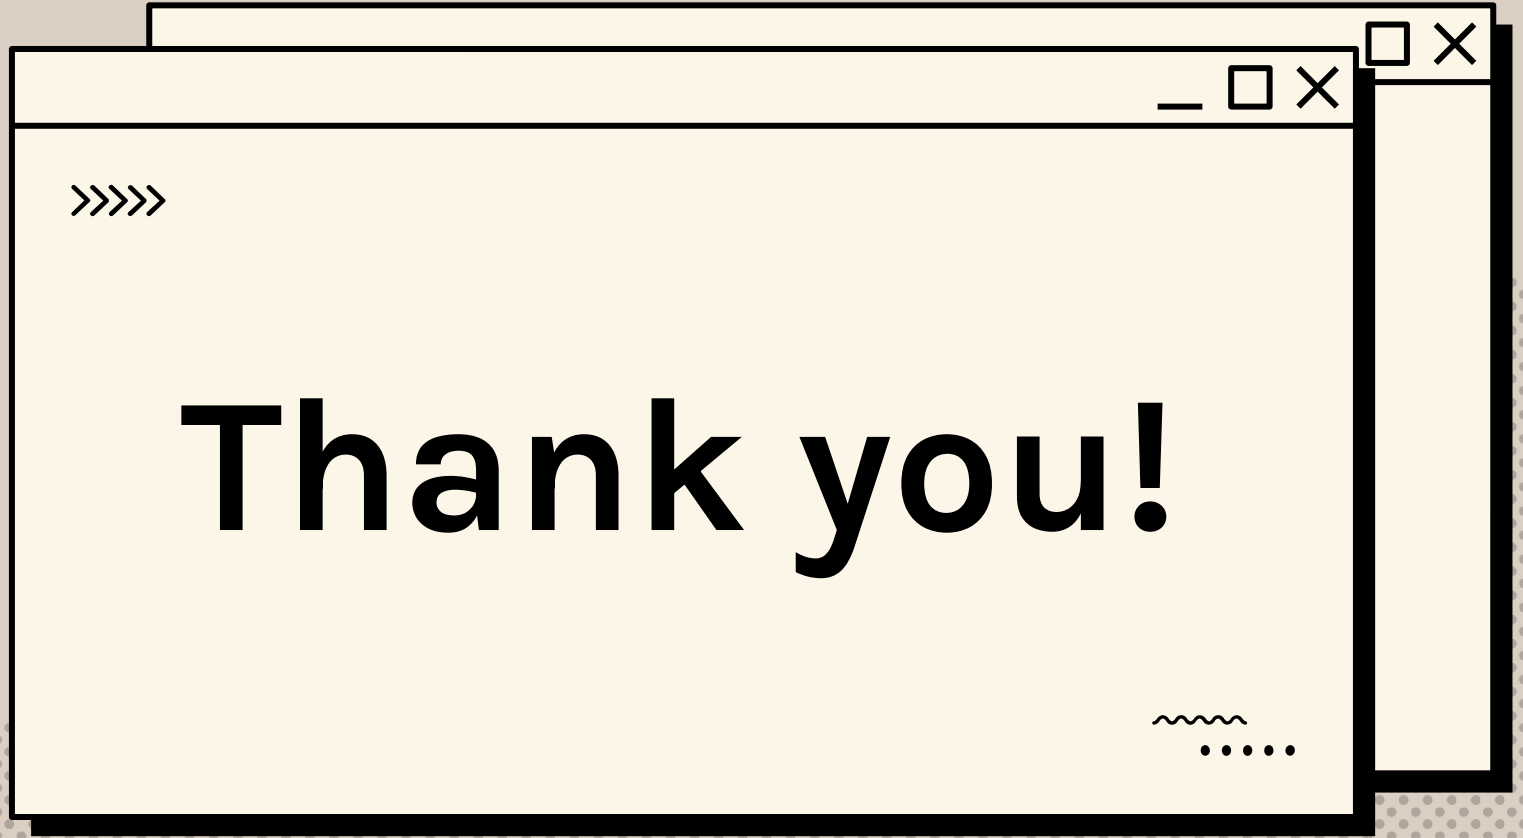

## Important:

- Motherboard why? Because without it how will the other parts work together
- Power supply(psu) why? Because without it the pc wont gain power thus cannot work

## Optional:

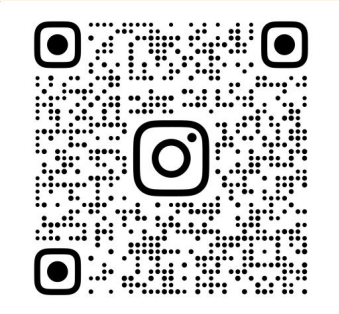

- Cpu cooler why? Because its just to cool your cpu, preventing it to overheat, but you can use the pc without one (NOT RECOMMENDED)
- PC case why? Because its just there to hold your motherboard, hdd, etc in place. No any functional uses other than that you dont need one just to start the computer.(unless if you want a very exposed pc and dusty one too, its not a good idea)

What is something you thought was not a computer?  
(optional)
